LAB-II TASK 2 lab Report

Student Information:

M Owais

Electrical Eng (Ai)

Registration No: BF25NWELE0708

Semester 2nd

Section B

Title:

Declaration and Display of a Floating-Point Variable

Objective:

To declare a floating-point variable named `pi`, assign it a value, and display it.

Theory:

A floating-point variable (`float`) is used in C++ to store real numbers or numbers with decimal points. These variables are important in scientific calculations where precision is required.

The value of π (pi) is approximately 3.14, which is commonly used in mathematical calculations involving circles and geometry.

Program (with comments):

```
#include <iostream>   // Library for input/output
using namespace std;  // Standard namespace

int main()
{
    float pi = 3.14;  // Declare float variable and assign value 3.14

    cout << "Value of pi is: " << pi << endl; // Display the value of pi

    return 0; // End of program
}
```

Explanation:

A float variable named `pi` is declared and assigned the value 3.14. The program then prints this value using the `cout` statement.

Output:

Value of pi is: 3.14

Conclusion:

This program shows how floating-point variables can be declared and used to store decimal values in C++.
